

MICROWAVE MONOLITHIC INTEGRATED CIRCUIT PACKAGE

Related Application

This application is based upon prior filed
copenending provisional application Serial No. 60/231,926
filed September 11, 2000.

Field of the Invention

This invention relates to microwave
monolithic integrated circuits (MMIC), and more
particularly, this invention relates to modules having
5 a microwave monolithic integrated circuit that can be
tuned for optimum performance and improved packaging of
a MMIC and transceiver module.

Background of the Invention

10 The recent explosion in wireless
telecommunications has increased the demand for high
performance millimeter wave radio frequency (RF)
modules. One of the major cost and yield drivers for
high frequency MMIC modules has been manual tuning to
15 optimize module performance. The majority of MMIC RF
amplifiers are not self biased. Therefore, each
amplifier requires gate voltage (V_g) adjustment to tune
the amplifier to its nominal operating conditions.
This tuning normally occurs after the amplifiers have
20 been assembled in the module and are connected to the
power supply.

In order to have access to the chips in the
module, probe stations are required. In addition,

[illegible]

Special pick-up tools with pick-in-place
30 equipment have been used to automatically pick-in-place
the MMIC chips. These tools are expensive to
manufacture and usually different MMIC chips require
different tools. This has presented a challenge to
different manufacturing companies because most
35 automatic pick-in-place machines are limited to a

These MMIC radio frequency modules also are built in low volume amounts because there are usually a high number of MMIC chips, substrates and peripherals that are installed in each module. For example, a typical millimeter wave transceiver would have about 10 to about 15 MMIC chips, 15-20 pieces of substrate, and about 50-60 other peripheral components, such as resistors and capacitors. There is also a requirement that each of the components be connected via wire or ribbon bonds. This has also presented the challenge to millimeter wave module manufacturing companies.

The present invention is advantageous and provides a microwave monolithic integrated circuit (MMIC) package that overcomes the disadvantages of the prior art as noted above. A base plate is matched as to its coefficient of thermal expansion (CTE) with the MMIC. A solder preform is contained on the base plate and is mounted on the solder preform. A chip cover covers the MMIC and the base plate and chip cover are configured with respective portions that engage each other such that any pads on the MMIC are exposed for wire and ribbon bonding thereto. The base plate and MMIC are secured together by a solder flow process from the solder preform.

The base plate can be formed from copper tungsten (CuW) or aluminum silicon (AlSi) alloy. It can be about 10 to about 15 mil thick. The chip cover can be formed of plastic and the solder preform can be formed from a gold-tin alloy. In one aspect of the

the invention, a solder preform is about 1 to about 2 mil thick. The base plate and chip cover can be secured to each other by the solder preform during a solder flow process. The base plate can include side rails that engage the chip cover. The chip cover includes overlapped rails that engage the chip cover.

Brief Description of the Drawings

Other objects, features and advantages of the present invention will become apparent from the detailed description of the invention which follows, when considered in light of the accompanying drawings in which:

FIG. 1 is a schematic circuit diagram of a self-tuned millimeter wave transceiver module of the present invention.

FIG. 2 is an exploded isometric view of a microwave monolithic integrated circuit (MMIC) package of the present invention.

FIG. 2A is a plan view of the MMIC package shown in FIG. 2.

FIG. 2B is a side elevation view of the MMIC package shown in FIG. 2.

FIG. 3 is an exploded isometric view of a multi-layer, thick film, millimeter wave radio frequency transceiver module, and showing the cover, channelization section, multi-layer thick film section, and the bottom plate.

FIG. 4 is an exploded isometric view of the various layers of the thick film section.

FIG. 5 is an exploded isometric view of a transceiver module, and showing the various connections.

Detailed Description of the Preferred Embodiments

The present invention will now be described more fully hereinafter with reference to the accompanying drawings, in which preferred embodiments of the invention are shown. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art. Like numbers refer to like elements throughout.

The present invention advantageously eliminates manual amplifier probing and module tuning in MMIC module manufacturing. By using low cost surface mount devices and a microprocessor, the RF module performance can be optimized in real time with no intervention for use in communications, radar, fiber optic, and other RF applications. The advantages include:

1. Optimization of RF MMIC amplifier operation without manual or automatic probing or tuning.
2. A simple low cost solution (< \$1) per amplifier that eliminates module probing and tuning.
3. Self-tuning that requires no die probing or testing.
4. Reduced RF module assembly and test at least by a factor of 5.
5. Chip level self diagnostics.
6. Transmitter gain and output power control without using attenuator chips.
7. Temperature compensation without the use of active attenuator.

8. Reducing/controlling the DC power dissipation as a function of output power, therefore controlling thermal conditions.

9. Testing RF power through the use of a power monitor circuit.

10. Using an embedded microprocessor for continuous real-time optimization of module performance.

11. User optimization of key module performance parameters without circuit design changes.

12. Shutting down the transmitter RF output (sleep mode) for safety without switching off the power supply.

13. Upgrading module performance via module software upgrade, i.e., a customer pays only for needed features.

14. Correcting for parts variation as a function of temperature and frequency using the on board EEPROM to store characteristics data.

FIG. 1 illustrates the low cost circuit used to self bias the MMIC amplifiers. The entire circuit is implemented using low cost commercial off the shelf (COTS) surface mount chips.

As illustrated, a schematic circuit diagram of the self-tuned millimeter wave transceiver module of the present invention is shown. The module includes a radio frequency MMIC chip formed as a module and illustrated by the dashed lines at 12 and a surface mounted digital microcontroller, indicated by the dashed lines at 14.

The MMIC module includes a plurality of amplifiers, as is typical with a MMIC chip, but only illustrates one amplifier 16. The radio frequency signal enters and passes through a filter 18 and into

5 can include a large number of amplifiers **16** on one chip, as known to those skilled in the art. The surface mounted digital controller **14** includes a digital potentiometer **20** having a nonvolatile memory circuit. An example of a potentiometer includes a
10 AD5233 circuit, as known to those skilled in the art. The potentiometer **20** can handle a bias voltage of about -3 volts.

to the amplifier **16** through the drain. The current sensor **22** is connected to a multi-channel sampling, analog/digital circuit **24**, such as an AD7812 circuit, as known to those skilled in the art. Other current sensors connect to other amplifiers (not shown) and connect to the multi-channel A/D circuit **24**. A temperature sensor **26** is connected to the multi-channel sampling A/D circuit and is operative for measuring the temperature of the MMIC module. A microprocessor **28** is included as part of the surface mounted digital controller, and operatively connected to an EEPROM **29** and other components, including the multi-channel sampling A/D circuit **24** and the nonvolatile memory digital potentiometer **20**. As shown, the potentiometer **20** is connected to other amplifiers on the MMIC and can step gate voltage for respective amplifiers and provide individual control.

As also illustrated, the radio frequency signal from the amplifier **16** can pass from passive coupler **30** to a power monitor diode or other detector

circuit **32** connected to ground. This connection from passive coupler **30** can be forwarded to the multi-channel sampling A/D circuit **24**.

The circuit shown in FIG. 1 adjusts
5 automatically the amplifier gate voltage (V_g) until the amplifier **16** reaches its optimum operating condition as measured by the amount of current drawn by the drain (I_d), and as measured by the detector circuit **32** at the output of the amplifier (if available). This is
10 achieved by controlling (through a serial digital interface) the Digital-to-analog (D/A) converter output voltage generated from potentiometer **20**. The D/A converter includes a nonvolatile memory and is currently available with four channels for less than \$3
15 at the current time.

As the gate voltage is varied, the current sensor **22** provides a voltage output that is proportional to the drain current drawn by the amplifier **16**. The current sensor output is digitized
20 by the multi-channel serial analog-to-digital converter (A/D) **24** that digitizes the drain current level. The current level word is compared to a pre-stored optimum amplifier drain current level, such as contained in the EEPROM **29**. The gate bias level is adjusted until the
25 optimum drain current is reached. The detector circuit, which is available either on the MMIC chip or could be added externally, provides a confirmation that the drain current setting is at the optimum level by measuring the output power. The detector output **32** is
30 compared to a pre-stored value that defines the expected nominal value at the output of the amplifier.

The drain current adjustment, the current sensing and detector output measurements can be implemented in a real-time continuous adjustment mode

2025 RELEASE UNDER E.O. 14176

Traditional methods of controlling gain and output power in RF modules has been to use active attenuators in the transmit chain. This is inefficient because any amplifiers in the chain will dissipate power. By using the digital potentiometer **20**, the gain and output power of each amplifier can be controlled individually or in groups. The present invention allows the module to have infinite control over gain and output power, without adding active attenuators after each amplifier, thus, reducing cost and eliminating unnecessary DC power dissipation.

5 sensed by a diode **32a**. The output of the diode **32a** is amplified and digitized via the serial A/D converter.

10 of temperature changes. This is accomplished by maintaining the pre-set current draw from each amplifier constant as the module temperature changes. With the present invention, the module gain and output power can be controlled with high precision.

15 A user's ability to program the module gain
at any stage in the circuit chain provides the
flexibility to trade-off key performance parameters,
such as transmitter noise figure (NF) versus
intermodulation level (IM), without changing the
20 circuit design. Real-time individual chip control also
allows the user to operate in a desired condition, such
as a linear mode for high modulation communications.

25 also be used on different devices with the MMIC chip,
such as a mixer, multipliers, and an attenuator. By
pinching off (maximum negative gate bias), all
amplifiers in the transmit chain can be highly
attenuated (over 50 dB) for safety reasons during
30 installation. The present invention requires no
additional switches or hardware.

The use of the microprocessor **28** and the chip control circuits as explained above allows the module manufacturer to enable only those features that a

customer desires for a particular application. Although the module hardware is identical, the module features will be controlled by software. This allows flexibility of using the same module in many different applications, including wireless point-to-point, point to multi-point or Vsat. Additionally, the use of the microprocessor and a standard interfaces allows programmability and software upgrades (for additional features) of the modules in the field without removing them.

The use of a microcontroller **14** with the associated microprocessor **28** and onboard EEPROM **29** allow for correction and tuning of various functions within the module. The corrections may include, but are not limited to (a) gain variation over temperature, (b) linearization of the power monitor circuit as a function of temperature and frequency, (c) gain equalization as a function of frequency, and (d) power attenuation linearization as a function of frequency and temperature. The use of a microprocessor **28** to control each of the active devices with the RF module, and the use of the EEPROM **29** to store correction factors, allow a high degree of flexibility and enables the module to operate with high accuracy and performance. Module characterization data (gain, power, noise figure) are collected over temperature and frequency during module testing. The correction factors are calculated automatically by a Test Station and stored in the EEPROM **29**. The correction factors are used during normal module operation to provide a desired performance.

The present invention also provides an improved MMIC chip package as shown in FIGS. 2, 2A and 2B. The MMIC package **40** has several advantages.

1. Protection of MMIC chips in coefficient of thermal expansion (CTE) matched packages.

2. Packaging of MMIC chips at very low cost.

5 3. Improved auto pick and placement, direct wire bonding and ribbon bonding, without causing damage to a fragile MMIC.

4. Improved chip performance (isolation) through miniature packaging.

10 5. An RF module housing formed of low cost material, such as aluminum.

FIG. 2 illustrates an exploded isometric view of the package **40**, and showing the MMIC chip **42** and a base plate **44** that is matched as to its coefficient of thermal expansion (CTE) with the MMIC. A solder preform **46** is contained on the base plate **44** and the MMIC is mounted on the solder preform **46**. A chip cover **48** covers the MMIC. As shown, the base plate includes opposing side rails **44a** that extend along a portion of formed edges to leave the end areas open. The chip cover **48** includes opposing and two spaced overlap legs **48a**. The opposing side rails **44a** and overlap legs **48a** are configured such that when the chip cover is placed over the MMIC chip **42**, solder preform **46** and CTE matched base plate **44**, the side rails and overlap legs engage the respective chip cover and base plate, as shown in FIGS. 2A and 2B, to form open areas at the top and side of the corners and to leave exposed any pads **50** on the MMIC for wire and ribbon bonding thereto.

30 The MMIC module production can be similar to surface mount technology by packaging the MMIC chips to facilitate handling of the chips. The base plate **44** is formed of low cost Coefficient of Thermal Expansion (CTE) matched material, such as a copper tungsten

alloy, CuW, or aluminum silicon alloy, ALSi, having a thickness of about 10-15 mil. The cover **48** can be made out of many types of material including plastic. A 1-2 mil solder preform (such as gold tin) is received on
5 the base plate **44**. The cover **48** is shaped in such a manner that it does not cover the chip input and output pads and the DC pads (gate and drain).

The base plate **44**, the cover **48**, the solder preform **46** and the MMIC chips **42** are delivered in
10 waffle packs or similar packaging. These packages are placed on an automatic pick and place (P&P) machine, as known to those skilled in the art. The P&P machine is programmed to pick the base plate and place it in a waffle pack, which can be used at a high temperature
15 for eutectic soldering (such as graphite), using temperature ranges known to those skilled in the art. The P&P machine picks and places the solder preform **46** into the base plate **44**. The MMIC chip is placed on top of the solder preform **46**. The cover is placed over the
20 top of the chip **42**. This process is repeated for every MMIC chip.

It is estimated that the total P&P per chip package would take about 10 seconds. The number of chips that can be packaged in a day using a single P&P
25 machine is well over 8000. The entire waffle pack with the package assembly, including the MMIC chips, is placed in a eutectic solder oven to flow the solder and attach the chip to the base plate and attach the cover to the base plate.

30 FIGS. 3-5 illustrate an improved radio frequency transceiver module using thick film technology, such as the low temperature cofired ceramic technology known as green tape. More particularly, FIG. 4 illustrates a multilayer substrate board **50**

having different layers of low temperature transfer tape technology (LTTT) sheets, including a DC signals layer 52, ground layer 54, embedded capacitors and resistors layer 56, solder preform layer 58 and top layer 60.

FIG. 3 illustrates how the different layers in FIG. 4 are combined to form a multilayer thick film substrate board 50 that is received on a base plate 62 with a channelization plate 64 and radio frequency cover 66. Isolation vias 67 are shown and illustrated. These vias can run across multiple layers down to the ground layer. They can be formed by techniques known to those skilled in the art.

FIG. 5 shows a MMIC transceiver module 70 with the waveguide interface 72 built into the channelization plate 64 and showing the intermediate frequency outputs 74, local oscillator input 76, intermediate frequency input 78, various DC pins 80, module connectors 82 and external connectors 84 on a CCA.

The present invention improves the MMIC module assembly process by using a low cost multilayer transfer tape thick film board 50 for attaching the MMIC chips 86 and embedding all the peripherals and electrical connections in the multilayer thick film. The present invention offer several benefits.

1. A new use of Low Temperature Transfer Tape Technology (LTTT) multi-layer board for MMW module design and fabrication.
2. Simplification of MMIC module assembly by reducing part count by a factor of five.
3. Reducing peripheral components count by embedding all resistors and capacitors in a multilayer thick film board.

4. Embedding electrical connections in the multi-layer board, there by reducing the number of wire and ribbon bonds.

5. Using a planar module configuration for ease of assembly, then attaching RF channelization after dies assembly.

6. Improving RF isolation through channelization, compartmentalization and ground vias.

7. Reducing housing cost by using wire-EDM method for channelization, instead of machining.

8. Directly attaching the SMA and K-connectors directly to the multilayer substrate board.

MMIC module production is made similar to surface mount technology by packaging the MMIC modules to allow complete automation of the assembly process. As shown in FIG. 3, the module is made up of the base plate **62**, multilayer alumina substrate **50** formed from the layers, a channelization plate **64** and a cover **66**.

The base plate **62** is a gold plated flat sheet of low cost CTE matched material, such as Cooper Tungsten (CuW), about 1/8 inch thick, in one aspect of the invention. The plate is only cut to size and requires no machining.

The multilayer substrate board **50** is fabricated using the Low Temperature Transfer Tape (LTTT) technology, such as similar to the green tape technology, as well known to those skilled in the art, similar to low temperature cofired ceramic (LTCC) sheets. The LTTT processing closely follows the steps used in well established multi-layer thick film processing, as known to those skilled in the art. The multiple dielectric printing per layer is replaced by a tape lamination step. Both gold and silver conductor systems can be used with LTTT. Interconnects and vias

are formed by techniques known to those skilled in the art.

Although the LTTT process for forming multilayer structures can be applied to a wide variety of dielectric materials and substrate, the material selected for this illustrated aspect of the present invention is a standard 96% alumina substrate. The special formulated conductor materials are screen printed on the alumina substrate, using standard thick film equipment and processing techniques developed for forming conductive interconnects and interlayer vias. The tape sheets are bonded to the substrate using a combination of heat and pressure.

FIG. 4 show an example of the type of layers that can be used to form the alumina board. The number of layers can be as high as 12. The layers could be formed on a base substrate (S), as illustrated, of the type known to those skilled in the art. Each layer is about 2 to about 4 mil thick, and typically about 3 mil thick, and can be used to carry low frequency RF signals, DC signals, ground, or embedded passive components, such as capacitors and resistors. Interconnect or ground vias can be implemented across one or more layers of LTTT film.

This multilayer LTTT alumina substrate is particularly attractive for use with GaAs chip because of its CTE coefficient (7.1). Also, this material has excellent thermal conduction (25-200 W/MK). The MMIC GaAs chips can be attached directly to the substrate using gold tin solder pre-forms or silver epoxy. In cases of thermal concerns, the chips may be attached directly to the base plate using CTE matched shims, or on top of thermal vias that are connected to the bottom surface. These vias can be formed by techniques known to those skilled in the art. For ease of assembly and

wire bonding, the top layer (3 to 4 mil thick) will have cut-outs made exactly to the size of the chips (see Figure 5).

The multilayer substrate costs on the average about \$1.5 to \$2.5 per layer per square inch. Up to 275 vias per square inch are possible.

The channelization plate **64**, in one aspect of the present invention, is formed of gold plated aluminum, although other materials could be used. The channels **64a** are cut out using wire EDM methods. The channels **64a** are created to provide the isolation required between the transmit and receiver signals and to generate a cut off to lower frequency signals. The RF cover is also made of gold plated aluminum.

FIG. 5 illustrates a MMW transceiver module including the surface mount circuit card assembly (CCA) used to provide the regulator/controller function. The SMA connectors are attached directly to the multilayer substrate. The RF interface waveguide is provided as part of the channelization plate.

The module shown in FIG. 5 can be assembled by the following technique as one non-limiting example.

1. Pick and place all the MMIC chips on to the multi-layer alumina substrate. The substrate should have all the low frequency signals connections, DC connections, ground connections, passive devices already embedded in the layers and the solder pre-form.

2. Pick and place the DC connector and the low frequency SMA connectors used for IF and LO signals.

3. Flow the solder in a vacuum oven to attached the MMIC die and the connectors to the substrate board. Silver epoxy may be used in place of the solder.

- This application is related to copending patent applications entitled, "**SELF-TUNED MILLIMETER WAVE RF TRANSCEIVER MODULE,**" and "**THICK FILM MILLIMETER WAVE TRANSCEIVER MODULE,**" which are filed on the same date and by the same assignee and inventors, the disclosures which are hereby incorporated by reference.
